Disproof of 'Throughput Bonus' or 'Fast-Lane' Objection

Chia-Yu Chang, **NOKIA** Bell Labs <chia-yu.chang@nokia.com>

Koen De Schepper, **NOKIA** Bell Labs <koen.de_schepper@nokia.com>

Bob Briscoe, Independent <ietf@bobbriscoe.net>

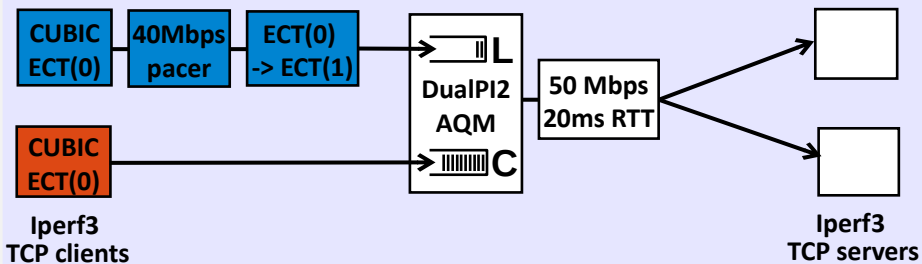

IETF tsvwg, May 2022

Background

- The objection* claimed the DualQ offers a 'fast-lane' or 'throughput bonus' and
"the bonus is easily exploited by unscrupulous senders without disabling congestion control"
- These claims were based on
 - a single experiment run with
 - no control experiment to check whether the alleged 'fast lane' was any faster than the other lane
- The following experiments aim to reproduce the objectors' experiment precisely
 - and to add control experiments

2 CUBIC flows; 1 "tweaked" flow joins after 10s

"tweaked" as described in objection

Left axis (Mbps)
— CUBIC(50Mbps) delivery rate
— CUBIC(40Mbps/ECT1 responsive) delivery rate
Right axis (ms)
— CUBIC(50Mbps) TCP RTT
— CUBIC(40Mbps/ECT1 responsive) TCP RTT

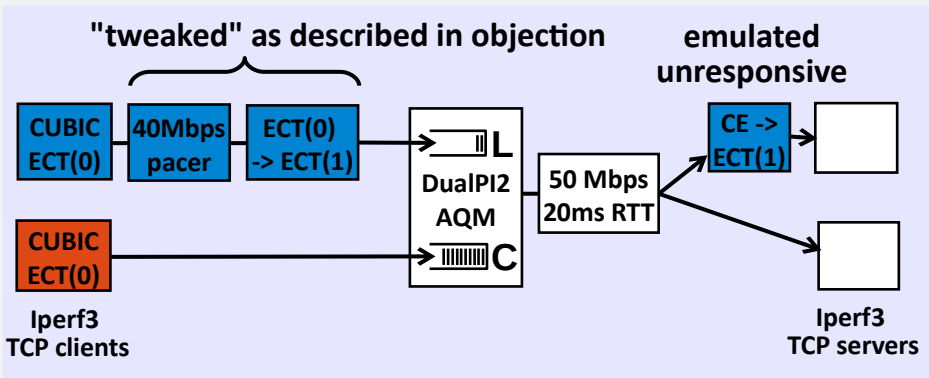

- Does not reproduce objection
- Tweaked flow gets significantly smaller capacity share (blue), not larger

L4S: CUBIC(50Mbps) vs CUBIC(40Mbps/ECT1 responsive)

qdisc:dualpi2 bandwidth:50Mbit rtt:20ms

Tweaked flow then also made unresponsive

Left axis (Mbps)

- CUBIC(50Mbps) delivery rate
- CUBIC(40Mbps/ECT1 unrespsn've) delivery rate

Right axis (ms)

- CUBIC(50Mbps) TCP RTT
- CUBIC(40Mbps/ECT1 unrespsn've) TCP RTT

- Reproduces objection very closely
 - but objection claimed cong. ctrl was not disabled
- Tweaked flow now gets 40Mbps (blue)
 - as expected for 40Mbps paced unrespsn've flow

L4S: CUBIC(50Mbps) vs CUBIC(40Mbps/ECT1 unrespsn've)

qdisc:dualpi2 bandwidth:50Mbit rtt:20ms

plot from objection for comparison

Control experiment: Tweaked flow unresponsive but ECT(0)

Left axis (Mbps)
— CUBIC(50Mbps) delivery rate
— CUBIC(40Mbps/ECT0 unrespns've) delivery rate
Right axis (ms)
— CUBIC(50Mbps) TCP RTT
— CUBIC(40Mbps/ECT0 unrespns've) TCP RTT

- Proves thru'put advantage is due to unresponsiveness, not DualPI2
- because tweaked flow (blue) gets same advantage in either queue

L4S: CUBIC(50Mbps) vs CUBIC(40Mbps/ECT0 unrespns've)

qdisc:dualpi2 bandwidth:50Mbit rtt:20ms

Summary

- No evidence for objectors' 'fast-lane' claim by reproducing their experiment
- The result can be reproduced v closely by suppressing congestion control
 - But objectors stated "bonus is easily exploited ... without disabling congestion control"
 - Objectors' experiment was likely faulty, and somehow suppressed congestion control
- Our experiments include a control run
 - Claimed 'fast lane' is no faster than the other lane
 - Dual Queue Coupled AQM meets its stated goal of not allowing unresponsive flows to cause more harm to existing traffic than in a single queue
 - unresponsive thru'put: same in either queue
 - unresponsive delay: lower in L than C queue, but not at the expense of anyone else's delay

Back-up Slides

Control expt #2: Tweaked flow ECT(0) and responsive

Left axis (Mbps)
— CUBIC(50Mbps) delivery rate
— CUBIC(40Mbps/ECT0 responsive) delivery rate
Right axis (ms)
— CUBIC(50Mbps) TCP RTT
— CUBIC(40Mbps/ECT0 responsive) TCP RTT

- Proves 40Mbps pacing is only a cap
- Because tweaked flow behaves:
 - as normal, given stable rate below 40Mb/s

L4S: CUBIC(50Mbps) vs CUBIC(40Mbps/ECT0 responsive)

qdisc:dualpi2 bandwidth:50Mbit rtt:20ms

Experiment details

- All nodes:
 - Ubuntu 18.04.4 LTS
 - Linux kernel 5.10.31-3cc3851880a1-prague-37
 - iproute2-5.9.0
 - Commit ID: testing/[6e042bcd4158](#)

Inside slide #3

2 CUBIC flows; 1 "tweaked"

Left axis (Mbps)
 — CUBIC(50Mbps) delivery rate
 — CUBIC(40Mbps/ECT1 responsive) delivery rate
 Right axis (ms)
 — CUBIC(50Mbps) TCP RTT
 — CUBIC(40Mbps/ECT1 responsive) TCP RTT

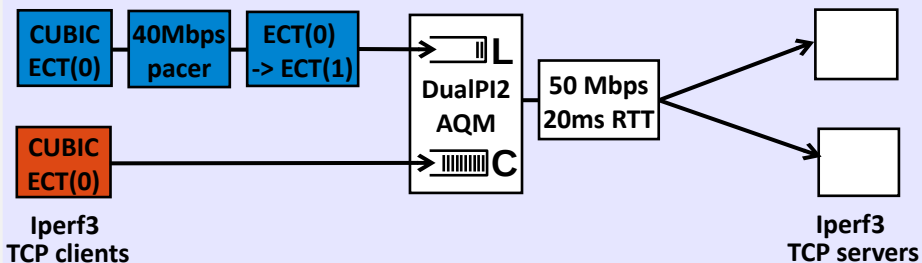

Mbps

ms

Prob (%)

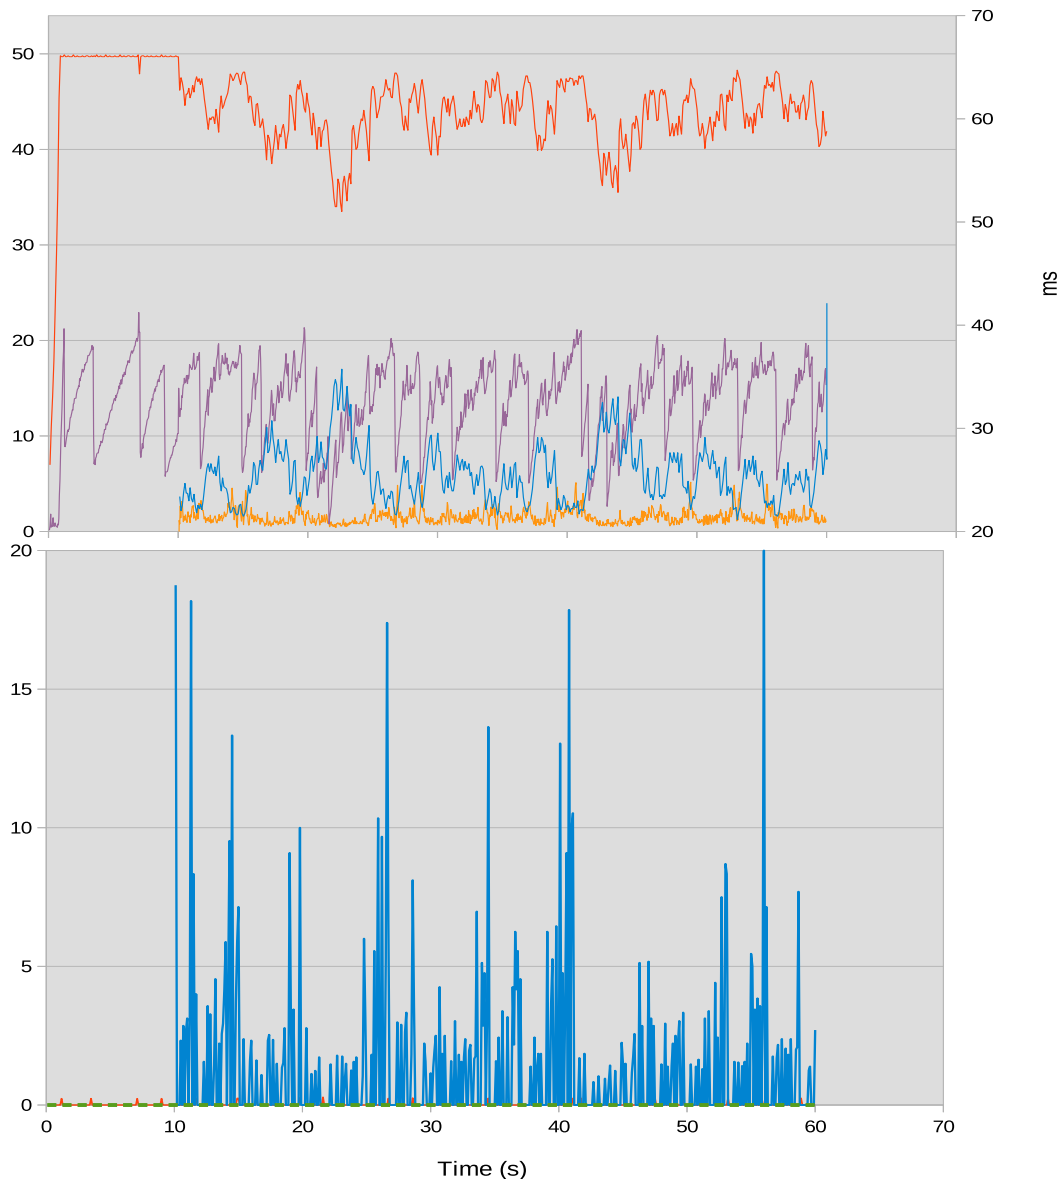

Time (s)

"tweaked" as described in objection

--- CE mark prob (L native)
 — CE mark prob (L coupled)
 — CE mark prob (C)

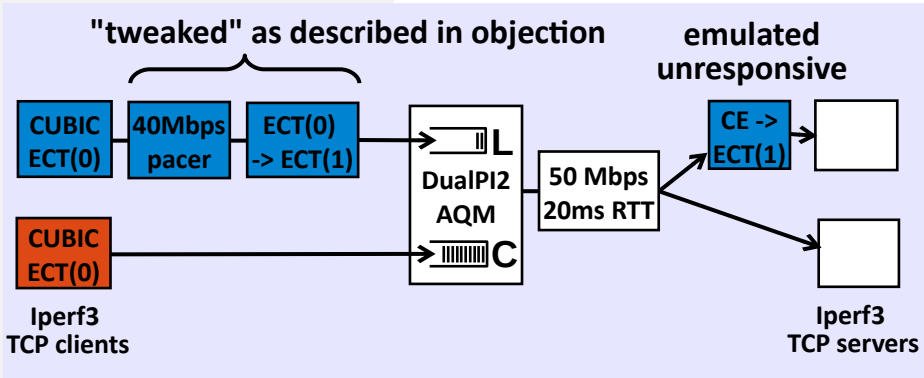

- Lower plot explains low thru'put of tweaked flow, due to its response to deliberately aggressive coupled marking (blue) instead of the Classic marking (red) intended for CUBIC
- zero native L4S marking (green dashed)

Inside slide #4

Tweaked and unresps'v flow

Left axis (Mbps)
 — CUBIC(50Mbps) delivery rate
 — CUBIC(40Mbps/ECT1 unresps've) delivery rate
 Right axis (ms)
 — CUBIC(50Mbps) TCP RTT
 — CUBIC(40Mbps/ECT1 unresps've) TCP RTT

--- CE mark prob (L native)
 — CE mark prob (L coupled)
 — CE mark prob (C)

- Lower plot shows that the unresponsive L flow squeezes the C flow into less capacity by causing
 - higher C congestion (red) and
 - in turn, higher coupled L congestion (blue) which it ignores
- Still zero native L4S marking (green dashed)
